Will Generative AI Make Us Stupid or Smart?

Benjamin Lira[a,1]

[a]University of Pennsylvania

Generative AI (GenAI) applications—especially those based on large language models like Gemini—are now ubiquitous, and their adoption rate is increasing. They represent the most advanced technology ever developed, matching or surpassing human performance in many complex tasks. As GenAI becomes embedded in our daily lives, it becomes crucial to understand its effects on how we think. I plan to explore how GenAI influences our cognitive processing, specifically by encouraging System 1 thinking, which is fast, associative, and automatic, vs. System 2 thinking, which is slower, resource-intensive, and deliberative.[1] I propose a series of experiments in which participants are randomly assigned to engage with a GenAI-chatbot or traditional web search in a judgment task. I then evaluate the effect of using GenAI on the quality of users' thinking and responses. This research will (1) examine whether interacting with GenAI encourages System 1 thinking, or if, alternatively, these interactions free up cognitive resources, allowing for increased System 2 processing; (2) identify the key mediators and moderators of this effect; and (3) develop interventions (i.e., changes to the GenAI user interface) that encourage more System 2 thinking when engaging with AI. This research will help elucidate how GenAI interactions shape our thinking, which will enable better alignment between GenAI systems and users.

Fifteen years ago, The Atlantic published an essay that went viral. It was titled "Is Google making us stupid?", and it argued that the convenience of internet search was reducing people's capacity for deep, critical thinking.[2] With the benefit of hindsight, it is clear that search engines did not spell the end of complex human thought, but rather made information more easily accessible. The rise of generative artificial intelligence now raises the question: "Is *GenAI* making us stupid?"

Without doubt, interacting with digital technologies can shape how we think. For instance, students randomly assigned to take notes on laptops perform worse on conceptual questions than students who take notes longhand[3]. Similarly, the use of search engines has been shown to influence memory processes. Even when directed to remember facts, we are more likely to forget them if we know they will be accessible in a computer; and may better remember *where* to access information rather than the information itself[4]. With long term use, technological tools can shape our brains. For example, drivers who use GPS more often have worse hippocampal dependent spatial memory during self-guided navigation, both cross-sectionally and longitudinally.[5,6]

The advent of GenAI. Generative AI refers to programs capable of generating seemingly new, meaningful content such as text, images, or audio.[7] For instance, you can ask Gemini to make a recommendation about U.S. budget allocations to foreign aid and, within seconds, receive a complete answer—not just a specific percentage of the budget but an eloquent and internally consistent essay justifying that proposal. Google Search, in contrast, generates a rank-ordered list of websites which you must visit individually, and process and integrate yourself to come to a conclusion.

Researchers are beginning to analyze the effects of GenAI tools in the workplace,[8–10] and results are mixed. Studies have sampled different kinds of work tasks, including writing,[8] customer support,[9] idea generation, and product innovation[10]. In studies where tasks are simpler (e.g., customer support calls[9]), using generative AI improves performance—especially for users at the bottom of the performance distribution. In more complex tasks, however, GenAI use leads to higher error rates[10]. Similarly, an analysis of 150 million lines of code, shows that since the inception of GenAI coding assistants, written code is more likely to be repeated, violating principles of code maintainability[11].

System 1 vs. System 2 cognition. Dual-process theories[1,12,13] provide a useful theoretical framework for understanding the beneficial vs. deleterious effects of generative AI on human judgment and decision making. These models posit that the mind has two ways of coming to judgments. System 1, characterized by associative pattern matching, is fast, effortless, and intuitive, underpinning our unconscious, automatic processes. In contrast, System 2 is deliberative, embodying our conscious, slow, and effortful cognitive activities that are more critical and reflective in nature. Take the following problem: A bat and a ball cost $1.10. The bat costs $1 more than the ball. What is the price of each item. Your System 1 intuition might be that the bat costs $1 and the ball 10 cents. If you work out the algebra step by step, your System 2 would realize that the only values that satisfy the equation are $1.05 and 5 cents. While there is debate regarding the details and the validity of this approach,[14–17] it is undeniable that when encountering problems, we sometimes think deeply, and sometimes do not.

What determines whether System 2 will become engaged? One contemporary account[18] posits that when formulating a judgment, System 1 produces intuitions and estimates the certainty of those intuitions. Certainty is lower when there are conflicting intuitions or when no intuition is strongly activated. If certainty exceeds a critical threshold, then a purely System 1 intuitive response will be produced. If, however, certainty drops below that threshold, System 2 is activated. In that case, the results of System 2 feed back into System 1, which in turn leads to the revision of the activation strengths of its intuitions and their certainty.

Often, System 1 yields correct answers more efficiently than System 2. Take for instance chess masters, who are able to intuit the right move, even though they have no better general working memory and search for plays no more extensively than novices.[19] Experts given repeated opportunities to learn from feedback develop intuitions that are more accurate than amateurs who deliberate on the same problems.[20] More generally, relying on "fast and frugal" thinking can be adaptive.[21–23]

On the other hand, relying on System 1 intuitions can also lead us astray.[1] System 2 deliberation is generally preferred when: a judgment is consequential, there is time available for deliberation, we are not an expert in the domain, and we cannot easily delegate the judgment to an expert[24]. Consider, for example, making the diagnosis of a complex medical condition, deciding on the strategic plan for a new tech venture, or judging the strengths and weaknesses of a potential new hire. Blindly accepting GenAI's suggestions may in complex cognitive tasks lead to suboptimal results.

How might interactions with GenAI influence system 1 vs. System 2 cognition. One possibility is that interactions with GenAI may encourage more System 2 thinking. Specifically, quick and complete answers to our questions may free up working memory, a rate-limiting necessity for System 2 deliberation[1,25,26]. In one study, taxing working memory by asking participants to remember a dot

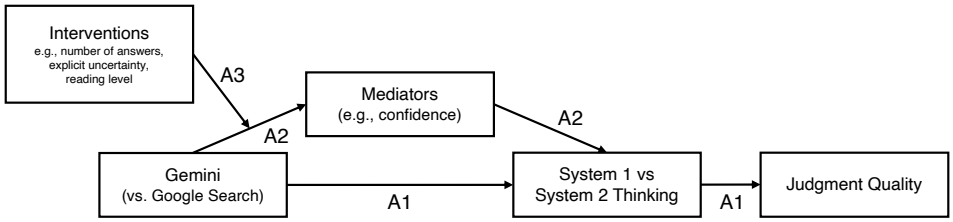

Fig. 1. Specific aims. Aim 1 (A1) seeks to establish the effect of GenAI interaction on System 1 vs System 2 thinking and judgement quality. Aim 2 (A1) explores the mediators of the effect. Aim 3 (A3) develops interventions to foster more System 2 thinking when engaging with GenAI.

pattern worsens performance on the Cognitive Reflection Task, a measure of System 2 (vs. System 1) thinking[27].

Alternatively, GenAI may encourage more System 1 thinking. Specifically, by producing answers that are complete and easy to process, GenAI may increase the user's estimate of the certainty of the GenAI response, a cue that *discourages* System 2 deliberation.[28,29] This possibility is consistent with prior research showing that we are more likely to unquestioningly accept something as true when it is more easily processed—a phenomenon known as fluency bias[30,31].

As shown in **Figure 1,** this proposal has three main objectives. In Aim 1, I will conduct a series of experiments comparing how using generative AI, relative to traditional web search, influences System 1 vs. System 2 thinking and the downstream consequences of these shifts on users' judgement quality and persuasiveness. In Aim 2, I will explore the psychological mechanisms by which generative AI changes the way we think. Finally, in Aim 3, I will design and test interventions to encourage GenAI users to engage System 2 thinking. Collectively, findings from these studies deepen understanding of the cognitive consequences of our evolving GenAI landscape and inform efforts to align GenAI technologies with users' most valued goals.

Aim 1: How does GenAI influence System 1 vs. System 2 thinking and judgment quality?

To establish whether interacting with GenAI encourages automatic (System 1) or deliberative (System 2) thinking, I will conduct a series of experiments in which adults and university students are randomly assigned to use either traditional web search (i.e., Google Search), or a GenAI chatbot (e.g., Gemini) to complete common judgment tasks. Following previous research[32], the extent of System 2 (vs. System 1) thinking will be measured by the time and effort users devote to produce their final judgments. The quality of users' final judgments will be assessed using third-party raters (both human and GenAI) or objective criteria (e.g., Brier scores).[33] In at least some of these studies, I will assess the degree of effortful cognitive processing via pupillometry[34–36] at the Wharton Behavioral Lab.

The basic procedure is shown in **Figure 2.** Participants will be asked to make a judgment on a topic (e.g., how much money should the U.S. government allocate to foreign aid?) and to write a short justification thereof. They will then be randomized to learn more about the topic, either by using Google or by interacting with a GenAI-chatbot like Gemini. Finally, all participants will be given the opportunity to revise their judgment and justification. I intend to use stimulus sampling[37] to make sure that results are not unique to a particular judgment task and GenAI model. See **Table 1** for a potential list of tasks, spanning judgment, decision, and forecasts.

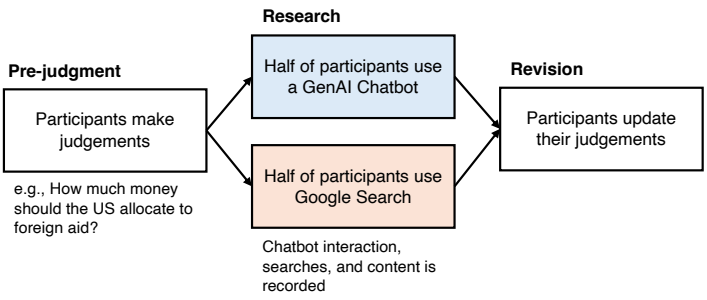

Fig. 2. Experimental task

Task Type	Example Tasks	Quality Metric
Recommendation	How much money should the U.S. government allocate for aid?	Human and GenAI raters
Forecast	How likely is it that the Russia-Ukraine conflict ends within the next year?	Brier Scores
Reasoning	Given this company's 5-year history (see case study for details), what is the most likely cause of its bankruptcy?	Human and GenAI raters

Table 1. Proposed judgement, forecasting, and decision tasks

To adequately power studies, I am working under the assumption that differences would be in the range of $.10 < d < .20$, which implies a sample size of between 395 and 1,570 participants in each condition to achieve power of 0.80.

Aim 2: What psychological mechanisms explain the influence of GenAI on System 1 vs. System 2 thinking?

In an overlapping set of experiments, I will in Aim 2 examine psychological mediators (e.g., feelings of fluency and certainty,[28]) that explain the effect observed in Aim 1.

Extending the methodology outlined in Aim 1, I will measure these mediators in two ways:

1. **User Perceptions.** Users will report how they perceived their interaction with the GenAI chatbot and the search websites.

2. **Natural Language Processing.** I will use natural language processing to identify psychologically-relevant features of GenAI responses that explain reduced deliberation (e.g., readability[38], tentativeness[39]).

Aim 3: What interventions can promote System 2 deliberation?

Leveraging insights from Aims 1 and 2, I will in Aim 3 develop and test interventions that encourage System 2 thinking when engaging with GenAI. For example, prompting GenAI to offer multiple and conflicting perspectives may encourage System 2 thinking by reducing user's subjective sense of certainty.

These interventions will target interface design and/or user interaction.

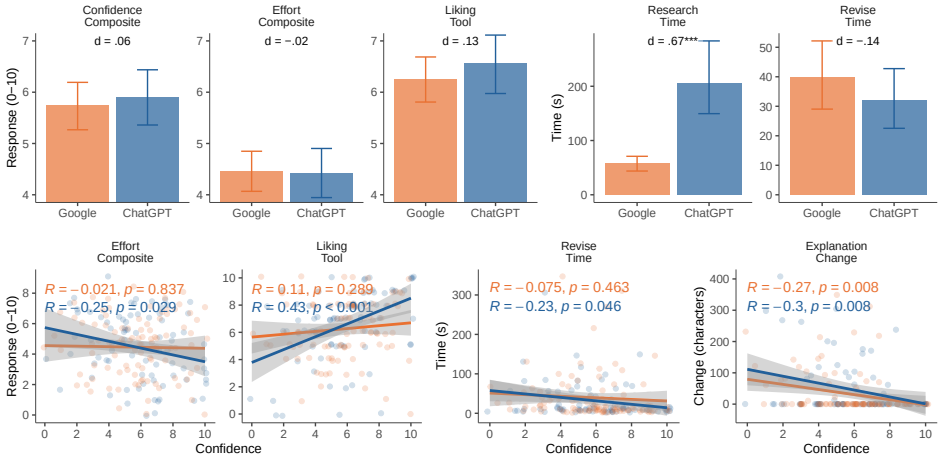

Fig. 3. Differences in user perceptions and engagement time of Google Search vs. Chatbot users in a judgment task. Correlations between closure and liking and effort metrics. REPLACE WITH CERTAINTY

1. **Interface design.** For example, prompting the GenAI chatbot to offer more than a single answer, explicitly model uncertainty, or write in differing levels of complexity might lead users to engage with more System 2 thinking.

2. **User interaction.** For example, users may be given strategies that are, ironically, similar to prompts we now give GenAI bots to generate more thoughtful, analytic answers. For instance, users may be asked to *make a plan before you give an answer, consider multiple solutions, write a pre-mortem plan on why your response could be wrong, etc.*

I compare the effectiveness of strategies aimed at users as well as the interface design. This line of work will be useful for designers building GenAI applications for situations where more deliberation is effective.

Pilot Data

As shown in **Figure 3,** preliminary pilot data ($N = 178$ adults) support the hypothesis that interacting with GenAI encourages System 1 thinking.

Participants provided a recommendation on the U.S. budget to foreign aid, were then randomly assigned to conduct research for as long as they wanted to using Google Search or a GenAI chabot*. Participants then returned and were able to revise their original recommendations, and their reasoning behind them.

Compared to participants who used Google search, participants assigned to the GenAI-chatbot spent 24% less time fewer seconds writing their revised response ($d = 0.14$), and reported exerting about the same effort ($d = 0.02$), despite having had done research for about four times as long ($d = 0.71^{***}$). Participants liked using the chatbot for research more than they did Google Search ($d = 0.13$), and they liked GenAI more when they felt it produced more certainty ($r = .43^{***}$). In GenAI users, certainty, in turn, predicted less self-reported effort ($r = -.25^{*}$), less revision time ($r = -.23^{*}$), and smaller changes to their answers ($r = -.30^{**}$).

Conclusion

The proposed research will illuminate how the rapidly changing capabilities of generative artificial intelligence will shape human cognition. From a **theoretical perspective,** it will elucidate some mechanisms that—with or without GenAI— prompt more automatic vs. more deliberative thinking. Additionally, it will inform the cognitive mechanisms behind the mixed effects of AI-augmentation on workplace performance[8–10]. In more **practical terms,** my findings will enable managers, individuals, and policymakers to harness GenAI's potential to enhance, rather than diminish, our cognitive capacities.

If this proposal is successful, it will open new avenues for research. Specifically:

Short-term spillover effects. First, do cognitive changes persist on an unrelated task immediately after the GenAI interaction is over?

Long-term effects on cognitive style. Second, does repeated interaction with GenAI produce enduring changes in cognitive style and learning motivation—and is the influence of GenAI greater for developing minds who grow up with GenAI tools vs. adults who did not?

Generalizability. Third, how does GenAI compare to other ways in which people get information, such as social media or face-to-face human interaction? Would the results generalize to engaging with GenAI through other interfaces such as smart email clients and word processors?

Will Gemini make us stupid? This proposal offers one way to think about how generative artificial intelligence will influence human cognition. However, it is just the beginning. The real questions are: when do these tools encourage us to be more deliberative and when do they do the opposite? What determines the direction of this effect? And how can we proactively craft tools that align our long-term interests with the short-term incentives of interacting with them? In other words: How can Gemini make us smart?

*Based on GPT-4. Future work will compare chatbots built using different large language models, including Gemini and LlaMa.

1. Will Gemini Make Us Stupid? - 1000 Character Abstract

Generative AI (GenAI) applications based on large language models like Gemini are now ubiquitous. As AI becomes embedded in our daily lives, it becomes crucial to understand how it influences how we think. I propose a series of experiments where participants are assigned to do research with an AI-Chatbot or traditional web search to explore how AI influences System 1 thinking, which is fast, associative, and automatic, vs. System 2 thinking, which is slower, resource-intensive, and deliberative. I plan to (1) establish whether the ease with which AI responses are processed encourages System 1 thinking, or whether the reduced cognitive load allows for increased System 2 processing; (2) identify the key mediators that drive this effect; and (3) develop interventions—targeting user interaction and interface design—that encourage more System 2 thinking. This research is pivotal for optimizing AI design to enhance user cognition and decision-making.

2. Describe the desired impact your research will make on the field and society, and why this is important to you. Include any personal, educational and/or professional experiences that have motivated your research interests.

I was already a grownup when smartphones and social media came along. I remember how exciting it felt to be in touch with friends and family members who lived many miles away. Today, this early excitement has given way to concern. I am constantly distracted by my phone. Social media drives political polarization around the world. Young people, especially girls, face mental health issues. A lively conversation after dinner is often replaced with sitting side-by-side staring into our phones and ignoring each other.

As we integrate ever more powerful generative AI (GenAI) into our daily lives, the lessons learned from past innovations weigh heavily on my mind. I often find myself chatting with GenAI models for leisure and work. Many of these interactions are fulfilling. Often, Gen AI helps me solve pressing problems in an instant, and sometimes I am surprised at how much I learn in the process. Other times, however, I find myself interacting with GenAI passively—lazily letting it tell me what to think or write, and thoughtlessly accepting its first suggestion.

More than we consciously realize, the way we think and behave is heavily dependent on the structure of our environments (Barker, CITE). This means that the way in which we design and engage with AI will determine whether it elevates our capacities for thought and engagement or the opposite.

Ultimately, I hope my research will help guide GenAI designers and users towards enriching human capabilities rather than inadvertently diminishing them. By understanding the mechanisms of how AI systems shape the way we think, we will be able to design interventions that help GenAI surface the best of us. My hope is that this knowledge will help steer our developing AI landscape closer to one where we can do more with our brains rather than less.

3. Describe an example of your leadership experience in which you have positively influenced others, helped resolve disputes or contributed to group efforts over time. (A leadership role can mean more than just a title. It can mean being a mentor to others, acting as the person in charge of a specific task, or taking the lead role in organizing an event or project. Think about what you accomplished and what you learned from the experience. What were your responsibilities? Did you lead a team? How did your experience change your perspective on leading others? Did you help to resolve an important dispute at your school, church, in your community or an organization? And your leadership role doesn't necessarily have to be limited to school activities. For example, do you help out or take care of your family?).

Without a fair bit of luck, I would not be where I am today. Very few graduates of Peruvian universities are admitted to PhD programs at world-class institutions. Language and culture aside, Peruvian scholars who dream of becoming scientists at the cutting edge don't have access to meaningful research experiences, and local universities lack the Ivy League pedigree.

I now have mentorship, resources, and opportunities beyond the wildest dreams of the boy I was growing up. I feel especially beholden to help those who—in one way or another—look like an earlier version of myself. My hope is that they, too, will benefit from an environment where their talents can be expressed. I have taken opportunities to advance this goal with undergraduate researchers and students navigating the graduate admission process, both from Peru and the US.

I have been lucky to work closely with undergraduate students exploring what psychological research looks like. At first, I was tempted to intervene too much, too soon. I quickly realized that my role was to make suggestions, provide feedback, and some support.

Likewise, I've been enriched by learning from PhD applicants. Providing feedback on their research statements and conducting mock interviews with them has allowed them to expand my own views. My questioning and probing have allowed them to refine their research programs.

It's easy to think that leadership is only about propelling a project forward by telling people what needs to be done. These experiences have taught me that leadership is often much more about listening, empathy, and connecting meaningfully with others. I am only powerful to help others when I listen to them, ask questions rather than give answers, and help others untangle their thoughts on their own.

I certainly put in a lot of effort and perseverance in getting to where I am. I was also extremely lucky. I hope I can contribute a little so that others from backgrounds like mine, might rely a little less on luck and more on a supportive community that I strive to nurture.

Technical Skills

Programming: Qualtrics, R, SPSS, Factor, MPlus, MLWin, Psychopy
Statistical Methods: Exploratory and confirmatory factor analysis, multilevel modelling, structural equation modelling, cluster analysis, polynomial regression with response surface analysis (RSA), nonparametric regression methods including logistic, poisson, and negative binomial regression, and machine learning methods including tress, random forests, penalized regression, boosting, support vector machines, deep learning, neural networks, autoencoders, generalized mixture models, k-means, reinforcement learning, text modelling (transformers, LDA, naïve bayes).

Work Experience

2020 – **Visiting scholar,** Duckworth Lab, University of Pennsylvania
Duckworth Lab, PI: Angela Duckworth
- Participated in all aspects of the research process: conceptualization, data collection, data analysis, writing, submission and revision.
- Mentored an undergraduate researcher and a group of high-school interns.
- Designed activities for an undergraduate course on motivation.
- Designed and taught a series of lessons on statistical analysis using R.

2016 – 2020 **Research assistant,** Pontificia Universidad Católica del Perú
Motivation and Emotion Research Group. Projects:
- Basic psychological needs and poverty
- Maternal autonomy support
- Basic psychological need support and thwarting and engagement in school and university
- Autonomy support intervention program
- Need support and thwarting in competitive sports

2015 – 2017 **Lead research analyst,** Cerebrum
- Was responsible for research and intervention programs.
- Taught and supervised graduate students' theses.
- Wrote articles for the education community.
- Participated in conferences.
- Developed content for graduate courses in educational neuroscience.

2016 **Statistical consultant,** EVACP Consulting
- Carried out psychometric and statistical analysis for a social program impact evaluation for the Peace Corps in Peru.

2015 – **Thesis advisor**
- Coached and supported +30 undergraduate and graduate students from Universidad de Lima, Pontificia Universidad Católica del Perú, Universidad Peruana de Ciencias Aplicadas in multiple stages of their thesis projects.

2014 – 2015 **Research and educational psychology intern,** Cerebrum
- Created an intervention program for the development of self-regulation and executive function and designed a tool to evaluate its impact.
- Developed content for graduate courses in educational neuroscience.

2013 **Assistant to Ricardo Braun Ph.D.,** Universidad de Lima
- Edited and reviewed a book manuscript about the philosophy of the mind.

2012 **Assistant to Sandra Inurritegui Ph.D.,** Universidad de Lima
- Designed the methodology, developed experiments, and coordinated school logistics.

Languages

Spanish: Native English: Advanced German: Basic

Additional Education

Foundations of Data Analysis – Part I. University of Texas at Austin. MOOC.
The Analytics Edge. MITx. MOOC.
Quantitative Biology Workshop. MITx. MOOC

Additional Projects

- #Investigatips. Video library explaining research methods and statistics. +55K video views. (In Spanish)
- Statistics for Psychologists with R. A series of self-guided tutorials and practice sets exploring common data manipulation, visualization, and analysis tasks in R. Collaboration with Chayce Baldwin
- R Package. Custom functions for ordinal alpha, Mahalanobis outlier detection, discriminant validity analysis, and data simulation.
- Natural Language Processing Tools. Custom R and Python funcitons and tutorials for Natural Language Processing in the Social Sciences.
- R Programming. Web application to predict grape harvest dates and volumes based on weather and agricultural data.

Community Service

- Volunteer for the program Un Techo Para Mi País, building houses after the Chincha 2007 earthquake. Constructed 5 houses for the benefit of 5 families.
- Volunteer for CPDI, a malnutrition prevention center in Pamplona. Worked with the community to generate appropriate strategies to promote healthy eating habits.
- One hundred and fifty hours of service in the IB-CAS program: building homes, tutoring children, among other service labors.
- Volunteer for the Peruvian Ministry of Education. Conducted interviews with teachers and principals regarding the effectiveness of feedback received by schools after the Census Student Evaluation.

Organizational Involvement

Member of Colegio de Psicólogos del Perú (National Association of Psychologists of Peru). CPsP. 31816

Test Scores

Graduate Records Examination (GRE) – Nov 14, 2019.
Verbal: 169 (99th Pc.), Quantitative: 166 (89th Pc.), Analytical Writing: 5.5 (98th Pc.)
Test of English as a Second Language (TOEFL): 119/120 – Sept 28, 2019.
Writing: 30, Speaking: 29, Reading: 30, Listening: 30.

Unofficial Academic Transcripts

I completed my bachelor's degree and professional licensure in Psychology at the University of Lima in Peru. I completed an academic exchange program during this time at Katholieke Universiteit Leuven (KU-Leuven), in Belgium.

Both the Peruvian and the Belgian grading system lies in a scale from 0 – 20, with 11 being the minimum passing grade.

Converted to US standards, I graduated with a 4.0/4.0 cumulative GPA, ranking first in my cohort. In the native grading system this was 18.6/20.

I've attached originals in Spanish alongside certified translations after this readable summary.

Class Name	Credits	Course Grade
2019—1		
Foundations of Mathematics	4	
Introduction to University Research	1	NA
Spanish Language I	4

secretary,

Prof. dr. Walter Schaeken

chair,

Prof. dr. Jan Elen

International Students Office
Faculty of Psychology
and Educational Sciences
Katholieke Universiteit Leuven
Dekenstraat 2 box 3702
3000 LEUVEN (Belgium)

Exam results are graded on a scale of 20. However in some cases the student may receive a code G to indicate that he/she has passed a part of the course for which there is no numerical grading. A code C indicates that a student has passed that course. A code T indicates that whereas a student has not passed that course he/she has still passed the year or programmae as a whole. A code V indicates that the student is exempted from that course. A code NA indicates that either the student did not sit the exam or did not complete the course. A code FR indicates that the student has been found to have cheated. A code NVT indicates that the course is no longer relevant for this student. A code GR indicates that there is no result yet for this course, but that a result is expected later on.

This report on your marks is provided purely as an extra service. In no way does it replace the study progress dossier that can be found on KU Loket, the only official source through which results and procedures of appeal are communicated.

1S = 1st Semester - 2S = 2nd Semester - AY = Academic Year

ECTS – European Credit Transfer System

KU LEUVEN Grading System

Duration of course unit:

AY = full academic year
1S = 1 semester during 1st semester
2S = 1 semester during 2nd semester

Description of the institutional grading system:

Individual grades are reported to the students on a scale ranging from 0 to 20.

ECTS credits for a given course are awarded (C) if a student gets a grade of 10 out of 20 (or higher). NA = Not Attended.

For students who pass the examinations, the grades have the following meaning:

- 10 or 11: sufficient;
- 12 or 13: satisfactory;
- 14 or 15: good;
- 16 or 17: very good;
- and 18 or more: excellent

ECTS grading scale:

ECTS grade	% of successful students normally achieving the grade	Definition
A	10	EXCELLENT - outstanding performance with only minor errors
B	25	VERY GOOD - above the average standard but with some errors
C	30	GOOD - generally sound work with a number of notable errors
D	25	SATISFACTORY - fair but with significant shortcomings
E	10	SUFFICIENT - performance meets the minimum criteria
FX	–	FAIL - some more required before the credit can be awarded
F	–	FAIL - considerable further work is required

CERTIFICATE

The University Director of Academic Services and Registration does here certify that

BENJAMIN LIRA LUTTGES

(Student ID 20092009) completed his studies in the Psychology Major in the period March-July 2015 and earned a cumulative weighted average (P.P.A.) of 18.633.

The equivalence in the above-mentioned major between the P.P.A. 20-point grading scale (0-20) and the G.P.A. (0-4) is given in the following table:

20-point grading scale	G.P.A.
11.0 to 13.89	2.0 to 2.49
13.9 to 4.99	2.5 to 3.49
15.0 to 15.99	3.5 to 3.99
16.0 and above	4.0

This certificate is issued at the request of the interested party to serve and avail as occasion shall or may require.
